

ABSTRACT

1 A substrate of label stock or the like has pressure sensitive adhesive on
2 one side, covered by release material. The release material is folded back or removed
3 along one edge of the substrate, exposing the pressure sensitive adhesive along that
4 edge. A transparent laminate is secured to the substrate by the exposed pressure
5 sensitive adhesive. A photograph of other document can be secured inside the device
6 by lifting the unadhered portion of the laminate, placing the photograph between the
7 laminate and the substrate, removing the release layer to expose the remainder of the
8 pressure sensitive adhesive layer, and pressing the photograph and laminate against the
9 lower substrate. The photograph is preferably smaller than the laminate product, so that
10 the laminate is secured to the substrate around all edges of the photograph. One or more
11 legs can be provided for positioning the device in an upright position.
